

A Code Sample

Enough to Understand the Code

- Assignment uses = and comparison uses ==.
- For numbers + */% are as expected.
 - Special use of + for string concatenation.
 - Special use of % for string formatting (as with printf in C)
- Logical operators are words (and, or, not) not symbols
- The basic printing command is print.
- The first assignment to a variable creates it.
 - Variable types don't need to be declared.
 - Python figures out the variable types on its own.

Basic Datatypes

Integers (default for numbers)

```
z = 5 / 2 # Answer is 2, integer division.
```

Floats

```
x = 3.456
```

- Strings
 - Can use "" or " to specify."abc" 'abc' (Same thing.)
 - Unmatched can occur within the string.

```
"matt's"
```

Use triple double-quotes for multi-line strings or strings than contain both 'and "inside of them:

```
"""a'b"c"""
```

Whitespace

Whitespace is meaningful in Python: especially indentation and placement of newlines.

- Use a newline to end a line of code.
 - Use \ when must go to next line prematurely.
- No braces { } to mark blocks of code in Python...
 Use consistent indentation instead.
 - The first line with less indentation is outside of the block.
 - The first line with more indentation starts a nested block
- Often a colon appears at the start of a new block.
 (E.g. for function and class definitions.)

Comments

- Start comments with # the rest of line is ignored.
- Can include a "documentation string" as the first line of any new function or class that you define.
- The development environment, debugger, and other tools use it: it's good style to include one.

```
def my_function(x, y):
    """This is the docstring. This
    function does blah blah blah."""
# The code would go here...
```

Assignment

- Binding a variable in Python means setting a name to hold a reference to some object.
 - Assignment creates references, not copies
- Names in Python do not have an intrinsic type. Objects have types.
 - Python determines the type of the reference automatically based on the data object assigned to it.
- You create a name the first time it appears on the left side of an assignment expression:

$$x = 3$$

 A reference is deleted via garbage collection after any names bound to it have passed out of scope.

Accessing Non-Existent Names

 If you try to access a name before it's been properly created (by placing it on the left side of an assignment), you'll get an error.

```
>>> y
Traceback (most recent call last):
   File "<pyshell#16>", line 1, in -toplevel-
        y
NameError: name 'y' is not defined
>>> y = 3
>>> y
3
```

Multiple Assignment

You can also assign to multiple names at the same time.

```
>>> x, y = 2, 3
>>> x
2
>>> y
3
```
